

Adding Items to a Dictionary: Updating Key-Value Pairs

Dictionaries are dynamic, meaning you can **add**, **update**, or **remove** items after the dictionary has been created. Let's explore how to add new items to a dictionary.

Start with creating a dictionary called `book` with some initial details:

```
book = {"title": "Pride and Prejudice", "author": "Jane Austen",  
        "year": 1813}  
print(book)
```

To make our dictionary more complete, we can add a new key-value pair to it. For example, we might want to add the `genre` of the book:

```
book = {"title": "Pride and Prejudice", "author": "Jane Austen",  
        "year": 1813}  
  
book["genre"] = "Romance"  
print(book)
```

After adding the new key-value pair, the dictionary now includes:

Key	Value
"title"	"Pride and Prejudice"
"author"	"Jane Austen"
"year"	1813
"genre"	"Romance"

Updating an Existing Key-Value Pair

If you need to update the value of an existing key, you can do so by reassigning a new value to that key. For example, let's assume the book's publication year was corrected to `1815`:

```
book = {"title": "Pride and Prejudice", "author": "Jane Austen",  
        "year": 1813, "genre": "Romance"}  
  
book["year"] = 1815  
print(book)
```

Note

Single `' '` and double `" "` quotes in Python are interchangeable and equivalent.
