

Challenge: Remove Whitespace from Strings

When working with categorical data in a DataFrame, extra whitespace at the beginning or end of string values can cause serious inconsistencies. For example, the values `"apple"`, `" apple"`, and `"apple "` may look the same to you, but Python treats them as different strings. This can lead to problems when grouping, filtering, or comparing data, and may result in incorrect analysis or missed patterns. Cleaning up these inconsistencies by stripping whitespace is a crucial first step in preparing your data for analysis.

```
import pandas as pd

data = {
    "Fruit": [" apple", "banana ", " cherry ", "date"],
    "Color": [" red", "yellow ", " red ", "brown"],
    "Count": [10, 5, 7, 3]
}

df = pd.DataFrame(data)
print(df)
```
