

Challenge: Drop Rows with Missing Data

When working with real-world datasets, you often encounter missing values represented as `NaN` (not a number). Deciding when to drop rows with missing data depends on the context and the importance of the missing information. Dropping rows is appropriate when the dataset is large enough that removing some rows will not significantly impact your analysis, or when the missing data is scattered randomly and does not represent a systematic issue. However, this approach can lead to loss of valuable information, especially if missing values are concentrated in a particular group or if the dataset is small. Always consider whether dropping rows could introduce bias or reduce the representativeness of your data.

```
import pandas as pd
import numpy as np

data = {
    "name": ["Alice", "Bob", "Charlie", "David"],
    "age": [25, np.nan, 30, 22],
    "city": ["New York", "Los Angeles", np.nan, "Chicago"]
}

df = pd.DataFrame(data)
print(df)
```
